

# Introduction to Bash programming/scripting

Jacques Dainat  
2015

# Summary

1) Shell ? What is that ?

2) Bash? What is that ?

3) Bash tricks

4) I/O and Redirection

5) Scripting in bash

6) Examples

**! Commands are in green (most of time)**

## Shell ? What is that ?

Shell = command-line interpreter (CLI) providing user interface ~1960

Windows : command prompt (command.com) until WinXP  
cmd (cmd.exe) Windows NT command interpreter

Unix : Bourne Shell (**sh**) – written by Stephen Bourne (released 1977)  
sh <-> standard

Shell available chronologically : sh (1977), csh (1978), tcsh (1981), ksh (1983), bash (1989),  
zsh (1990).

BASH = Bourne-again shell (GNU project - Free )

large offspring - unix family (e.g BSD, Linux, OS X, etc.)  
- Mac: OS X < 10.3 **tcsh**  
OS X >= 10.3 **bash**

CLI occurred at the same time as the keyboard.

Windows and Unix are operating systems

Command prompt is often called MS-DOS or / DOS that is in reality the Operating system name.

The Bourne shell was one of the major shells used in early versions of the Unix operating system and became a de facto standard.

## Shell ? What is that ?

List all the available shells :

```
cat /etc/shells
/bin/bash
/bin/sh
/bin/tcsh
/bin/csh
```

Check your default shell:

```
echo $SHELL
```

To switch from one shell to another, just enter the name of the new shell in the active terminal.

To know the current shell working, type: `echo $0`

Which Bash version ? `/bin/bash -version`

- OS X Yosemite (Bash 3.2 )
- Bash 4 exists since 2009

associative arrays available since bash 4

## Bash? What is that ?

Why BASH ?

- By default on most used Unix machines (Ubuntu, OS X)
- It can run almost all Bourne scripts and POSIX compliant scripts
- Syntax simplified :
  - Single [] are posix shell compliant condition tests.
  - Double [[]] are an extension to the standard [] and are supported by bash and other shells (e.g. zsh, ksh).
  - They support extra operations (as well as the standard posix operations).
  - For example: || , && and regex matching with =~ (Perl syntax).
- Associative arrays (since version 4)
- Free (GNU project)

**POSIX: Portable Operating System Interface, standard specify for compatibility with variants operating systems**

# Bash tricks

## The commands:

- Despite they are often intuitive you have to learn them.
- You may look the `/bin` and `/usr/bin` directories that contain all the commands.
  - `ll /bin`
  - `ll /usr/bin`
- Internet is your friend (e.g.):
  - OS X command line : <http://ss64.com/osx/>
  - Linux command line : <http://ss64.com/bash/>
- Have a “lazy dog”

!! Use **man**, **help** or **info** to see documentation of each command  
`man command`

`/bin` essentially contains command require by the system for emergency repairs, booting

`/usr/bin` contains the rest

**man**, **help** or **info** In that corresponding prioritization

# Bash tricks

General:

**Environment variables** hold values related to the current environment.

**env**

- **PATH:** It specifies the directories in which executable programs are located

**~/.bashrc** or **~/.profile** (file read when open a new shell)

- typically used to change prompts, set environment variables, and define shell procedures.

e.g: \* modified the PS1 variable to customize the prompt

<http://www.cyberciti.biz/tips/howto-linux-unix-bash-shell-setup-prompt.html>

\* add alias: `alias ll='ls -lGrt'`

`alias milou='ssh user@milou.uppmx.uu.se'`

\* Modify or add environment variables

**source ~/.profile** #take in account the modification in current shell

-lGrt: l for long format ; G for enable colorized output ;t to sort by time modified (most recently first); r for Reverse order - the oldest entries first (newest last = bottom)

# Bash tricks

## General:

- Use the tabulation key for auto-completion !
- **egrep**, **fgrep** and **rgrep** are often available but their direct invocation is deprecated (Is provided to allow historical applications that rely on them to run unmodified). Instead use **grep -E**, **grep -F** and **grep -r**.
- Need of calculation, type **bc**
- Pattern matching != Globbing  
Both use Wildcards but the first is for text matching while the second for file names.  
**/!\ Same Wildcard doesn't have the same meaning.**  
e.g: \*  
Pattern matching follows the Perl syntax.

Wildcards are also called metacharacters.

\* The preceding item matches 0 or more times.

\* Zero or more characters

# Bash tricks

Command substitution: ``command``  
`$(command)`

Bash replaces the command substitution with the standard output of the command.

The output of the command can be used in another command:

```
echo The current working directory is: `pwd`
```

or to set a variable:

```
var=$(pwd)
```

# I/O and Redirection

## Input

### from command line argument:

- file:                      - string:                      - nothing:  
**cat file\_input**        **echo "Hello world"**        **ls**                      ! Often commands accept supplementary option(s)

### from a stream (STDIN):

- file:                      - output of another command:  
**cat < file\_input**                      **awk '{if(\$1=="value") print \$0}' file** | **wc -l**  
Command 1                      Command 2

Command chaining tool.

Piping the STDOUT of a command into the STDIN of another.

/!\ commands that take an input either from a **file** or from **STDIN**: **grep, sed, cat, head, sort, wc, etc.**

/!\ commands that never read STDIN : **ls, cp, mv, date, who, pwd, echo, cd, etc.**

/!\ commands that read only **STDIN**: **tr**

**standard streams** are preconnected input and output communication channels

# I/O and Redirection

## **Output**

By default 3 *files* are opened with their descriptor, *stdin* (0), *stdout* (1), and *stderr* (2).  
(descriptors 3 to 9 stay available)

STDOUT redirection to a file:

**command** *file\_Input* 1> *file\_Ouput*

**command** *file\_Input* > *file\_Ouput*

>>

2> or 2>>

&> or &>>

2>&1

/!\ overwrites the *file\_Ouput* if exists

Appends the file *file\_Ouput*

to redirect *STDERR*

to redirect *STDOUT* and *STDERR*

Redirects *STDERR* to *STDOUT*

STDOUT of a command into the STDIN of another:

Piping |: awk '{if(\$1=="value") print \$0}' file | wc -l

Command 1

Command 2

Redirecting by cross-connecting streams.

Open a new descriptor: `exec 3<file` for reading (example with `read: while read -u 3 line;do echo $line;done`) - close it: `exec 3<&-`  
: `exec 3>file` for writing - close it: `exec 3>&-`

Redirection tutorial: [http://wiki.bash-hackers.org/howto/redirection\\_tutorial](http://wiki.bash-hackers.org/howto/redirection_tutorial)

## I/O and Redirection

Piping is powerful, but inappropriate if you need several command STDOUTs to feed the input of another command.

Process substitution: `<(command)`

Useful when a command needs a list of file as input.

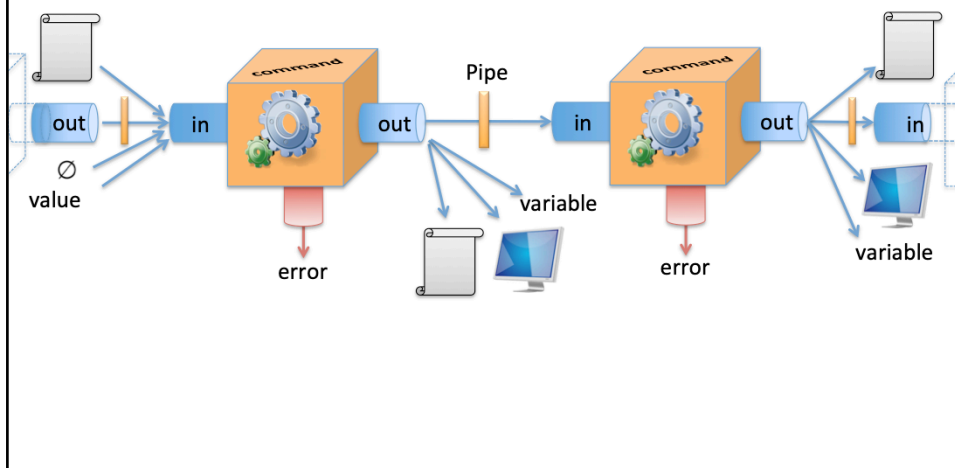

**It generates a file.**

```
diff <(ls $dir1) <(ls $dir2)
```

To check where the created temporary file is you can try: `echo <(command)`

# I/O and Redirection

Resume IO:

Example of process substitution in output: `tar cfv >(bzip2 -c > dir1.tar.bz2) $dir1`

# Programming in Bash

Lot of things can be done by command line:

```
command1 input1 outputFile1 ; output2=$(command2 outputFile1) ; command3 $output2
```

Command 1
Command 2
Command 3

```
command1 input1 outputFile1 ; command2 outputFile1 | command3
```

Command 1
Command 2
Command 3

When command2 doesn't handle file:

```
command1 input1 outputFile1 ; output2=$(cat outputFile1 | command2) ; command3 $output2
```

Command 1
Command 2
Command 3

Sub-command

```
command1 input1 outputFile1 ; cat outputFile1 | command2 | command3
```

Command 1
Command 2
Command 3

Same thing if command3 cannot Handle a STRING (as with **cut**) we should write: ;  
**echo \$output2 | cut -d" -f1**

Commands can contain control structures as Loop or if condition.

# Programming in Bash

In command line or in a script you can use these syntaxes:

`command1 ; command2` Several commands in a line

or

`command1`  
`command2` } One command by line

`command1 | command2` Several commands in a line with STDOUT redirection

or

`command1 |`  
`command2` } One command by line with STDOUT redirection

# Programming in Bash

## When used bash ?

### /!\ Not adapted when:

- Resource-intensive tasks
- Complex application
- Need of specific library or data structure
- Cross-platform portability required
- ...

- ⇒ Great for small programs
- ⇒ More **scripting** rather than programming

### Nice because:

- directly available via the terminal
- Easy to make script when you know command line. (automate routine)
- File handling
- System and Administrative
- Job Control
- ...

*use C or Java for cross platform portability*

# Programming in Bash

Script or command line ?

**Command line:**

- + short task
- + specific task (Throw-away code)
- if long command => hard to debug ; hard to read
- variable may be mixed up with those setup previously
- no user interface (check of arguments, help, etc)

**Script:**

- + long tasks
- + re-usable
- + code structured => easy to read (comment, block of code, function)
- + more user friendly (Warning, check of parameters)
- + debug easier
- big collection of scripts may be annoying (lost time to find the good one)

# Programming in Bash

## How write a script ?

### 1) Open a file to write your script with .sh extension:

<code>#!/bin/bash</code>	<- It's needed at the top of the file to specify the shell interpreter
<code>echo "This is my first script" #display the sentence</code>	<- One command (No semicolon needed)
<code># save the command in a variable, then print it</code>	<- A comment
<code>var=\$(pwd); echo "my working directory is \$var"</code>	<- One command (No semicolon needed)

### 2) Save the file and give the execution right.

```
chmod 754 myscript.sh
```

### 3) Execute your script:

```
./script.sh
```

# Programming in Bash

## 2,5 primary data structures

### Simple variables:

A variable in bash can contain a number, a character, a string of characters.

You have no need to declare a variable, just assigning a value to its reference will create it.

**`variable="a string with space"`** or **`variable=54`** or **`variable=$(command)`**

### Array:

**`array=()`** or **`array=(Anna Par Ulla)`** or **`declare -a array`**

/!\ The array is not initialized to empty in the last case if it already exists.

➤ Array index is an integer starting from 0.

### Associative array (only with Bash>4):

**`declare -A array`** or **`array =([string1]=value1 [string2]=value2)`**

/!\ problem if you try to do: **`variable=54 toto`**      **`<= bash try to execute «toto»`**

-bash: toto: command not found

# Programming in Bash

## Array manipulation commands:

<code>array[N]=value</code>	Set the element <i>N</i> of the array <i>array</i> to <i>value</i>
<code>array+=(value1 value2 value3)</code>	Append the array with three values.
<code>echo \${array[N]}</code>	Display the element referenced by the index <i>N</i> from <i>array</i> .
<code>echo \${#array[N]}</code>	Display the length of the value referenced by the index <i>N</i> in <i>array</i>
<code>echo \${#array[@]}</code>	Display (number of elements) of <i>array</i> .
<code>echo \${!array[@]}</code>	Display each <i>array</i> index key as a separate argument.
<code>echo \${array[@]}</code>	Display all the values stored in <i>array</i> .
<code>unset -v array[N]</code>	Destroy the <i>array</i> element at index <i>N</i> .
<code>unset -v array</code>	Destroy the complete <i>array</i> .

This slide is really boring... I know

# Programming in Bash

## Calculation in bash

**`(( var = operation ))`** or **`var=$(( operation ))`**

Assign the result of an arithmetic evaluation to the variable *var*.

**/!\ Natively Bash can only handle integer arithmetic.**

## **Floating-point arithmetic:**

You must delegate such kind of calcul to specific command line tool as **bc**.

**`echo "operation" | bc -l`**

Display the result of a floating-point arithmetic.

**`var=$((echo "operation" | bc -l))`**

Assign the floating-point arithmetic result to the variable *var*.

# Programming in Bash

**Bash Control Structures**    1) Conditional statements (on arithmetic values):

```
if (( condition1 ));then    / \ The spaces are important in that syntax
   command1
elif ! (( condition2 ));then
   command2
elif (( condition3 )) && (( condition4 ));then
   command3
elif (( condition5 )) || (( condition4 ));then
   command4
else
   command5
fi                    Logical operators are in green.
```

# Programming in Bash

**Bash Control Structures**     1) Conditional statements (on string values):

```
if [[ condition1 ]];then     / \ The spaces are important in that syntax  
    command1
```

```
elif ! [[ condition2 ]];then  
    command2
```

```
elif [[ condition3 ]] && [[ condition4 ]];then  
    command3
```

```
elif [[ condition5 ]] || [[ condition4 ]];then  
    command4
```

```
else  
    command5
```

```
fi                     Logical operators are in green.
```

# Programming in Bash

## Bash Control Structures

### 1) Conditional statements (next):

```
variable=$(command)
```

```
case $variable in
```

```
  pattern1)
```

```
    commands1
```

```
  ;;
```

```
  pattern2|pattern3|pattern4)
```

```
    commands2
```

```
  ;;
```

```
  patternN)
```

```
    commands3
```

```
  ;;
```

```
  *)
```

```
    commands4
```

```
  ;;
```

```
esac
```

Number of case infinite. It is a good alternative to if when lot of case to check.

# Programming in Bash

Bash Control Structures      2) The loops:

A) **The for loop:**

Loop over list of elements (files or values):

```
for i in file1 file2 file3; do
    echo "this is one file $i"
done
```

```
for i in *.fasta; do
    command
done
```

Loop over file's lines:

```
for i in $(cat file.txt); do
    echo "this is one line: $i"
done
```

Loop over array:

```
for i in ${!array[@]}; do
    echo "key : " $i
    echo "value:" ${array[$i]}
done
```

# Programming in Bash

Bash Control Structures      2) The loops:

## B) The *while* loop:

Loop over file's lines:

```
while read line ;do
    echo "this is one line: $line"
done < file
```

Loop over array:

```
i=0
while (( i < ${#array[@]} ));do
    echo "key : " $i
    echo "value:" ${array[$i]}
    ((i++))
done
```

=> It exists the useless **until** loop. Become a while loop by simply negating the condition.

# Programming in Bash

## Processes control :

ps ax     process status with a = show processes for all users  
          x = show processes not attached to a terminal

jobs     List the active jobs

Fg       Switch a job running in the background into the foreground.

bg       Restart a suspended job, and run it in the background

Kill     Terminate a process

times   System times for processes run from the shell

Wait     Wait for the specified process and report its termination status....

# Programming in Bash

What about library ?

Bash is quite limited but you can define a list of methods in a file. To include all the methods of this file in a script you have to write at the top of your script one of these lines (after the `#!/bin/bash`):

```
./path/to/the/file
```

```
$include /path/to/the/file
```

```
source /path/to/the/file
```

A book ? => **bash Cookbook (O'Reilly)**

## Examples

- 1) Reverse complementing
- 2) Get last two columns of a file
- 3) Remove isoform from proteome
- 4) Awk and join commands
- 5) Example of job control
- 6) downsampling a fastq

## Correction: Reverse complementing

```
echo sequence | rev | tr "ACGT" "TGCA"
```

Or

```
cat file | rev | tr "ACGT" "TGCA"
```

## Correction:

### Get last two columns of a file

```
awk '{print $NF"\t"$(NF-1)}' file
```

Or

```
rev file | cut -f1,2 | rev
```

## Correction: Remove isoform from proteome

Remove isoforms:

```
#!/bin/bash
```

```
#This script kept only one isoform per gene for proteomes coming from Ensembl
```

```
# Arguments and Paths
```

```
#####
```

```
if (( $# != 2 )) ; then
```

```
    echo -e "The script allows to filter proteome in fasta format from Ensembl with aims to keep the longest isoform per gene !"
```

```
    echo -e "The script needs 2 parameters: \n(1)The proteome input fasta file"
```

```
    echo -e "(2)The cleaned proteome output in fasta format"
```

```
    exit
```

```
fi
```

```
# Program heart:
```

```
cat $1 | awk '/^>/ {if(N>0) printf("\n"); printf("%s\t", $1"\t"$4);N++;next;}{printf($0);} END {if(N>0) printf("\n");}' | awk -F '\t' '{printf("%s\t%d\n", $0, length($3));}' | sort -t ' ' -k2,2 -k4,4nr | sort -t ' ' -k2,2 -u -s | cut -f 1,2,3 | awk '{print $1"\t"$2"\n"$3}' | fold -w 60 > $2
```

## Correction: Remove isoform from proteome

Explanation of the script "remove isoforms":

- 1) `cat $1 | awk '/^>/ {if(N>0) printf("\n"); printf("%s\t",$1"\t"$4);N++;next;} {printf($0);} END {if(N>0) printf("\n");}' | \ #linearize fasta and print col1 col4 and seq linearized`
- 2) `awk -F '\t' '{printf("%s\t%d\n",$0,length($3));}' | \ #extract length on the 3th column`
- 3) `sort -t ' ' -k2,2 -k4,4nr | \ #sort on column2, inverse length`
- 4) `sort -t ' ' -k2,2 -u -s | \ #sort on column 2, unique, stable sort (keep previous order)`
- 5) `cut -f 1,2,3 | \ #cut 3column`
- 6) `awk '{print $1"\t"$2"\n"$3}' | \ # print col1 col2 col3 separated by tabulation`
- 7) `fold -w 60 #pretty fasta = 60 letters per line`

! Can also be written on command by line with pipe at the end of each line.

`awk '/^>/ ... <=` every time there is the superior character  
`printf("%s", $0); =>` %s non useful

# Awk and join command

Exercise from Matthew Webster Perl course:

[http://blog.websterlab.eu/courses/perl/exercises/hashe\\_and\\_regular\\_expressions/](http://blog.websterlab.eu/courses/perl/exercises/hashe_and_regular_expressions/)

Exercise 3

<http://blog.websterlab.eu/courses/perl/exercises/8-control-structures/>

Exercise 2 from question 5

## Process control example:

```
# Launch training test
nbjobl=0
for (( i=$mini; i<=$maxi ; i=i+$interval)); do
    bsub -J trTe$i "augustus --gff3=on --species=$species$i $testFile$nbGeneRef | tee
    $traingFile${i}Test.out > started.trte$i"
    ((nbjobl=nbjobl+1))
done
echo "nb launched jobs = $nbjobl"

sleep 5
nbjobs=1
while [ $nbjobs != 0 ]; do
    nbjobs=$(bjobs | grep -c "trTe")
    echo "nb training test jobs running= $nbjobs"
    sleep 30
done
```

In the for loop it's possible to launch a determined number of job. And check the number of job running each Xsecondes. If number job running inferior to nubere job authorized, launch a new job.

## 6) Downsampling a fastq

How get a random sample of a dataset ?

Correction:

```
paste f1.fastq f2.fastq | \ #merge the two fastqs
awk '{ printf("%s", $0); n++; if(n%4==0) { printf("\n"); } else { printf("\t"); } }' | \ #merge
by group of 4 lines
shuf | \ #shuffle
head | \ #only 10 records
sed 's/\t\t\n/g' | \ #restore the delimiters
awk '{print $1 > "file1.fastq"; print $2 > "file2.fatsq"}' #split in two files.
```
